Many people forget or have difficulty finding information they need to make decisions. A security warning message may be used to increase personal identification on identification badges. Most studies on the impact of warning messages have focused on laboratory or health care settings. The current study measured the magnitude of the biasing effect of a security warning message in a physician's office waiting room. This is the first known study to measure the magnitude of the effect of a security warning message. A factorial design was used that factored in the presence and absence of a security warning message, as well as four personal attributes as manipulations that would represent security and nonsecurity credentials. The warning message effect was measured as the difference in the rate of identification by the badge with and without the warning message. A security warning message was associated with an 8% decrease in identification rates. There was no evidence of an interaction between the warning message and the personal attributes. Elevated expressions of insulin-like growth factor (IGF)-binding protein-3 and cysteine-rich protein 61 in hepatobiliary cancers and their clinical relevance. Insulin-like growth factor (IGF)-binding protein-3 (IGFBP-3) and cysteine-rich protein 61 (Cyr61) are secretory proteins that have been suggested to function in tumorigenesis. We evaluated IGFBP-3 and Cyr61 expression in the hepatobiliary tract and assessed the influence of these factors on the prognosis of patients with carcinoma of the gallbladder, bile duct, and liver. Immunohistochemistry and in situ hybridization were performed to evaluate the expression of IGFBP-3 and Cyr61 in normal and tumor tissues of the hepatobiliary tract from 235 patients with different tumor stages. The results were correlated with a variety of clinicopathologic parameters and patients' outcomes. 570a42141b
