DNA barcoding is a powerful method based on specific short regions of DNA to help identify biological organisms quickly and efficiently. It has been widely used in taxonomy and biodiversity studies, and increasingly it is also applied in molecular systematics, functional genomics and ecological studies. Although barcode-based approaches have been used for years, in the last decade they have been rapidly adopted, and several countries and organizations worldwide have begun to promote standardization of barcoding projects, which guarantees fair access to biological resources. DNA barcoding has already proven its value in different fields: it has been used to estimate species richness in plants, animals and fungi, and to unveil cryptic biodiversity in these groups. Furthermore, a growing number of animals have been identified using barcoding approaches, such as plants, fungi, and insects. Here, we review the history of DNA barcoding, describe its current practices and give examples of its application in current taxonomic and ecological studies. Finally, we discuss how DNA barcoding could be used in the future to help manage, conserve and understand biodiversity.Genetic variability of hepatitis B virus DNA in Brazilian chronic carriers. The variability of hepatitis B virus (HBV) in chronically infected patients is demonstrated by the phylogenetic heterogeneity of the virus. The aim of this study was to analyse the genetic variability of the virus in Brazilian chronic carriers with different clinical manifestations. Hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg) negative individuals, which were positive for hepatitis B virus-DNA (HBV-DNA) by polymerase chain reaction (PCR), were investigated by PCR and restriction fragment length polymorphism analysis (PCR-RFLP). Four different patterns of HBV-DNA amplification were identified. The prevalence of HBV genotypes in all individuals was a similar to that previously described in the literature. The most frequent genotype was B, representing 77.1% of all the cases. Genotype F and G were the

2; d2[1] -= 3; } if (cond) { if (cond) d1[2] += 5; d2[2] += 7; } else { d1[2] -= 5; d2[2] -= 7; } } This  
construct, `if (cond) do { if (cond) d1[i] += 2; d2[i] += 3; } while (cond);`, is valid in C and Java, but  
invalid in D. In D, conditionals are equivalent to `@if(cond)`, and `while (cond)` is equivalent to  
`@while(cond)`. Since we don't allow `@while` on blocks, this special form cannot be used with it.

You can take a sequence of blocks and apply `@if` to each. The syntax for `do-while` is rather  
strange: `int[] a =... for (int i : a) {... } // incorrect` The effect of this is a loop that terminates once  
condition is false. One would expect it to be more like `for (int i : a) {...;`
